

## ABSTRACT

The present invention provides a reinforcing holder against  
5 vibrations mounted on the joining parts of structural members such  
as foundations, columns, beams and cross-beams to reinforce them so  
that a wooden building may not be broken down even if strong  
vibrations caused by an earthquake, a typhoon or the like are loaded  
thereupon. The reinforcing holder against vibrations comprises a  
10 reinforcing base member 1 having fixing pieces 11 and 11 formed by  
twisting and bending both end parts of a plate formed of high tension  
steel in one direction, and a bent and swelled part 13 or a curved and  
swelled part 14 formed in the intermediate part thereof, and  
absorbing members 2 having rubber elasticity. The reinforcing base  
15 member 1 is fixed to structural members A via the absorbing  
members 2.
